PROPOSAL DESCRIPTION

Motivation

With the increasing population the demand for skilled and reliable workers is increasing day by day. Lets say you are enjoying your cup of coffee and the main electricity fuse breaks down now you are sitting with no electricity and a load of work on your head. The first thing you have to get fixed is the fuse which requires a skilled electrician but you don't know an electrician. You make ask any of neighbors or even search online but you don't have any reliable method to contact the skilled worker or you can just rely on these methods.

*Here comes **Skill Mitra** a digital marketplace just like amazon for skilled workforce where you can connect to different workers on various services and compare different people on the basis of their profile and reviews.*

The Motivation Behind our model is to create a platform which is easy to use for both the workers and the consumer making the consumer have a variety of options and for the workers a medium to get work.

State of the Art / Current solution

At this moment, the available solution for an unexpected equipment malfunction is limited to contacting the neighbors in search of a reliable connection, searching for relevant contacts on general websites, or calling local agencies. But the problem is that every solution has some of its own problem sometimes it can be luck sometimes it can be expensive. There exist a solution where people are listed but the problem is that their information is not available about their work etc. Also their are local people doing this job but they add some extra costs and require lot of time. So the current standard of services allows people to rely on their luck and hope that the called person will be competent and not take advantage of the situation.

The limitations are as follows-

- *Unstructured Online platforms*
- *Word of Mouth recommendation*
- *Unfair Pricing*

Project Goals and Milestones

Our project aims to solve the problem of hiring a worker by establishing a platform, where homeowners can communicate directly with available workers and avoid extra charges for middlemen services. The web interface will enable contractors to configure their rates, conditions, and obtain feedback from clients. With this we can find a carpenter, plumber, and other local professionals easily. We are designing our web interface with java mainly using java libraries such as spring boot or bootstrap etc also to store the data we will use MySQL to store data of the skilled workforce and the users. Our main idea is to develop a online web interface that will work as a marketplace for skilled workforce.

Stages are-

1. Designing the basic schema or diagrams
2. Developing The SRS document
3. Coding
4. Connecting the API
5. Testing of the interface created

Project Approach

We want to develop a web marketplace where the workforce can connect to consumer. This will help both parties to solve their own problems such as difficulty in finding work and for the consumer to get a worker based on his/her own choice.

For our PBL evaluation 1 we create a basic diagram of our model what kind of libraries we will be using, and enrolling into different courses to gain knowledge for the interface.

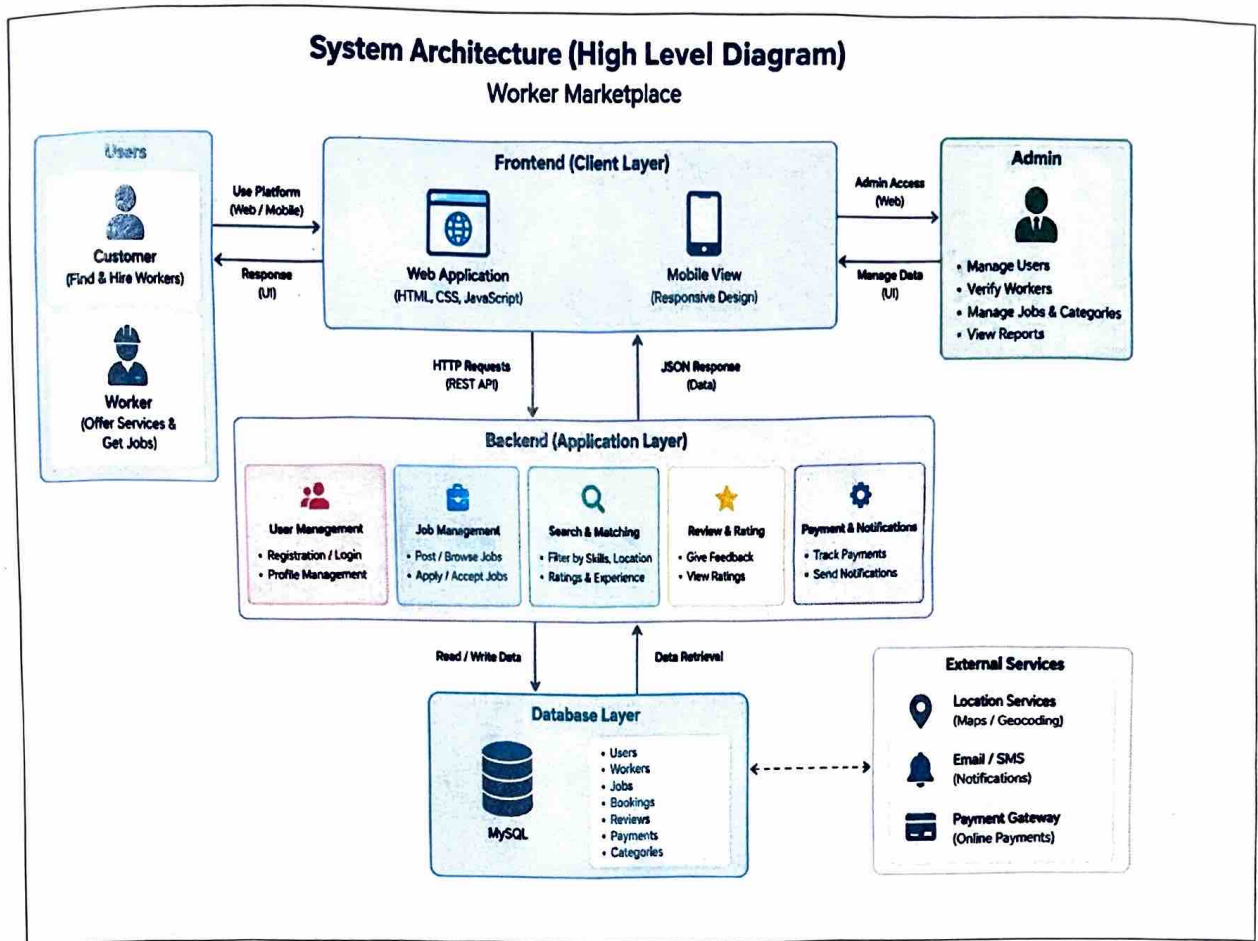

For our PBL evaluation 2 we will start developing the coding part creating the code for java program and sql database. Further gaining knowledge on different libraries which will be used. Our approach to create a 3 page interface for the admin. Worker and consumer.

For our last evaluation we will be working on the testing on the web interface making sure the api is working well and connected and there is no error in the output.

The 3 phase approach-

1. Planning
2. Development
3. Testing

System Architecture

Project Outcome / Deliverables

SkillMitra will offers local workers a digital platform to get work based on their expertise while setting prices of their choice without any additional costs. We are designing an interface which will help both the consumers and the workers in the own ways. We are choosing Java as the main tech stack in our interface which will be easy to understand as there is low knowledge of tech in the workforce and a minimal design for both users.

Also SQL will be used to store the data of the different users so that they can access their information any time

The application will be designed using Java as the programming language, Spring Boot framework, and MySQL database.

So the main outcome will be a platform where workers can connect with their required workplace it will give them an opportunity to get some work solving unemployment

Assumptions

In Skillmitra we assume that the people have access to smartphones and know a little about technology. This will help them to use the interface without any problems.
Also their will be consumer feedback for their work.
Adding a way to show payment methods.
